

Project README

Functionality of entire project can be described as under:

- 1) It generates 15 unique and diverse real estate listings using GPT 3.5 Turbo instruct model
- 2) We take the real estate listings output, process it and store it in pandas dataframe format and then save it into csv format (listings.csv and listings_1.csv)
- 3) We load the contents of listings_1.csv and create langchain documents out of it and then create embeddings and populate chroma db with embeddings
- 4) Next we take input from users and form query (ask_questions_query function)
- 5) Using the query in step 4 we run similarity search across vector database and return top 2 matching document(semantic_search function)
- 6) Next we use the matching document obtained in step 5 to created augmented listing(gen_aug_listing function)
- 7) run_app function combines the functionality described in step4, 5, and 6 above. The way we use it is – just run run_app function with template. It calls the function described in steps 4,5,6. This is our main app function. It is required that step 3 is completed before running this function.
